# Building the Web Api

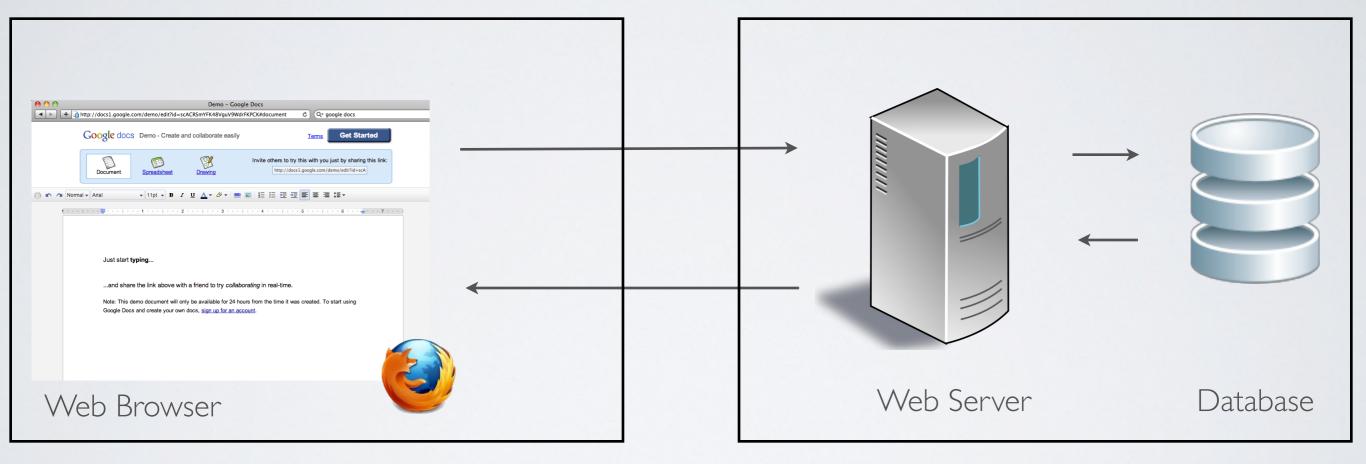

Thierry Sans

# The HTTP protocol

#### Anatomy of a Web Application

#### Client Side

#### Server Side

#### The HTTP protocol

Network protocol for requesting/receiving data on the Web

- Standard TCP protocol on port 80 (by default)
- URI/URL specifies what resource is being accessed
- The request method specified with a command

#### Let's look at what a web server does

```
telnet to a web server
> telnet www.utsc.utoronto.ca 80
GET /
         enter HTTP requests
```

#### Anatomy of a URL

#### HTTP Request Methods

- **POST** add an unidentified resource
- PUT add a an identified resource
- **GET** get a resource
- PATCH update a resource
- **DELETE** delete a resource
- and others HEAD, TRACE, CONNECT, OPTIONS

#### HTTP Request

- Method POST, PUT, GET, PATCH, DELETE ...
- Query String
- Headers key/value pairs
- [optional] Body data

#### Using the command curl

- \$ curl options url
  - -v verbose
  - -- request request method
  - --data request\_body
  - --header header

#### HTTP response

- Status code
- Headers key/value pairs
- [optional] Body data

#### HTTP response status codes

- 1xx information
- 2xx success
- 3xx redirection
- 4xx client error
- 5xx server errors

#### Method properties

#### An HTTP request/response

- may have a <u>request body</u>
- may have a <u>response body</u>
- may not have side effects a.k.a <u>safe</u>
- may have the same result when called multiple times a.k.a <u>idempotent</u>
- → the choice is left to the programmer

#### What the standard recommends

Method	Request Body	Response Body	Safe	Idempotent
POST			X	(X)
PUT			X	
GET	X			
PATCH			(x)	(X)
DELETE	X		(X)	

# Building an HTTP server with Node.js

#### Node.js

- Runs on Chrome V8 Javascript engine
- Non blocking-IO (a.ka asynchronous, a. k.a event-driven)
- No restrictions (unlike when js is running on the browser)

#### Example

src/node/readfile.js

```
import {readfile} from 'fs'

readFile('helloworld.txt', 'utf8', function(err, data) {
   if (err) console.log(err)
   return console.log("output 1")
});

console.log("output 2")
```

console

```
$ node example.js
output 2
output 1
```

#### Building an HTTP server with Node.js

src/node/httpserver.js

```
import { http} from 'http'
const PORT = 3000
function handler(req, res){
    console.log("Method:", req.method)
    console.log("Url:",req.url)
    console.log("Headers:", req.headers)
    res.end('hello world!')
createServer(handler).listen(PORT, function (err) {
    if (err) console.log(err)
    else console.log("HTTP server on http://localhost:%s", PORT)
});
```

#### Routing HTTP requests

Process HTTP requests and execute different actions based on

- the request method
- the url path
- whether the user is authenticated
- ect ...
- A router can be written from scratch (but it is tedious)
- Use the backend framework Express.js

#### Express.js - HTTP Methods

src/express-examples/0 I\_httpmethods.js

```
import { createServer} from 'http'
import express from 'express'
const app = express()
const PORT = 3000
// curl localhost:3000/
app.get('/', function (req, res, next) {
    res.end("Hello Get!")
});
// curl -X POST localhost:3000/
app.post('/', function (req, res, next) {
    res.end("Hello Post!")
})
createServer(app).listen(PORT, function (err) {
    if (err) console.log(err)
    else console.log("HTTP server on http://localhost:%s", PORT)
});
```

#### Express.js - Routing based on the path

src/express-examples/02\_routing.js

```
// curl localhost:3000/
app.get('/', function (req, res, next) {
    res.end(req.path + ": the root")
});
// curl localhost:3000/messages/
app.get('/messages/', function (req, res, next) {
    res.end(req.path + ": get all messages")
});
// curl localhost:3000/messages/1234/
app.get('/messages/:id/', function (req, res, next) {
    res.end(req.path + ": get the message " + req.params.id)
});
```

#### Express.js - body encoding

The body of HTTP request and response is a string

- → **Problem:** how to send data structure between the frontend and backend?
- → **Solution:** encode them either using:
  - ✓ URI encoding (sometimes used) see src/express-examples/04\_body-uri-encoded.js
  - ✓ XML encoding (rarely used these days)
  - ✓ JSON encoding (very frequently used these days)
    See src/express-examples/05\_body-json-encoded.js

## JSON

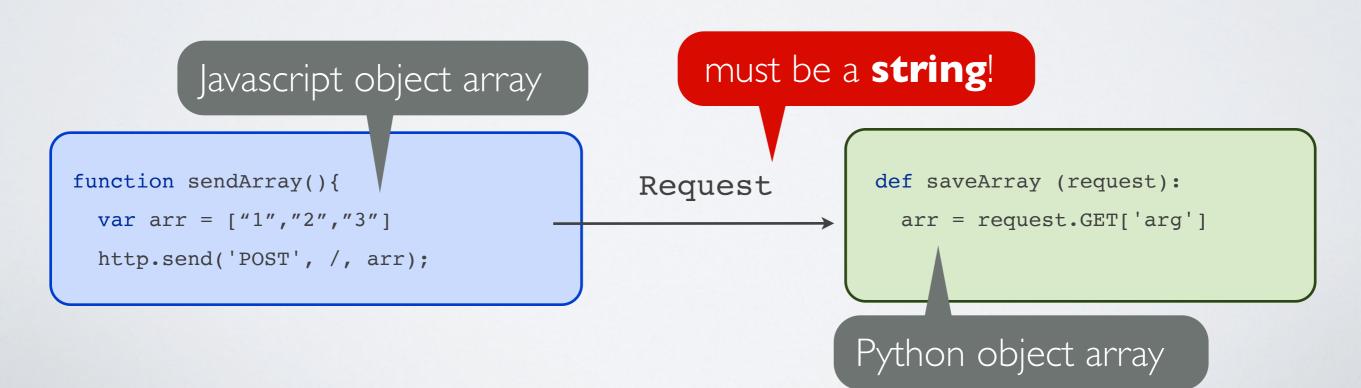

### JavaScript Object Notation

Thierry Sans

#### Sending structured data

How to send a structured data (arrays or dictionaries) through an HTTP request or response?

- Only strings are send back and forth
- ✓ Have a string representation of a complex data structure

#### Why do we need JSON?

Original idea: using XML

✓ In practice: JSON is used for its simplicity

#### The JSON standard (RFC 4627)

- · Lightweight open format to interchange data
- Human readable
- Used for serializing and transmitting structured data over a network connection (HTTP mostly)
- Since 2009 browsers support JSON natively

#### Anatomy of JSON

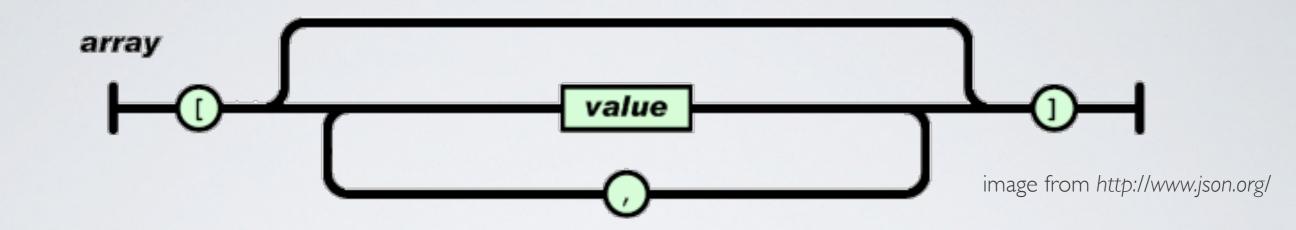

A JSON data structure is either

```
array (indexed array)
object (associative array)
```

JSON values are
 string - number - true - false - null

#### JSON Array

or

```
{"name": "Thierry"},
    {"name": "Jeff"},
    {"name": "Bill"},
    {"name": "Mark"},
]
```

#### JSON Object

}

```
object
                                                                image from <a href="http://www.json.org/">http://www.json.org/</a>
"firstName": "John",
"lastName": "Smith",
"age": 25,
"male": true
"address":
     "streetAddress": "21 2nd Street",
     "additionalAddress": null
     "city": "New York",
     "state": "NY",
```

"postalCode": "10021"

#### JSON in Javascript (natively supported)

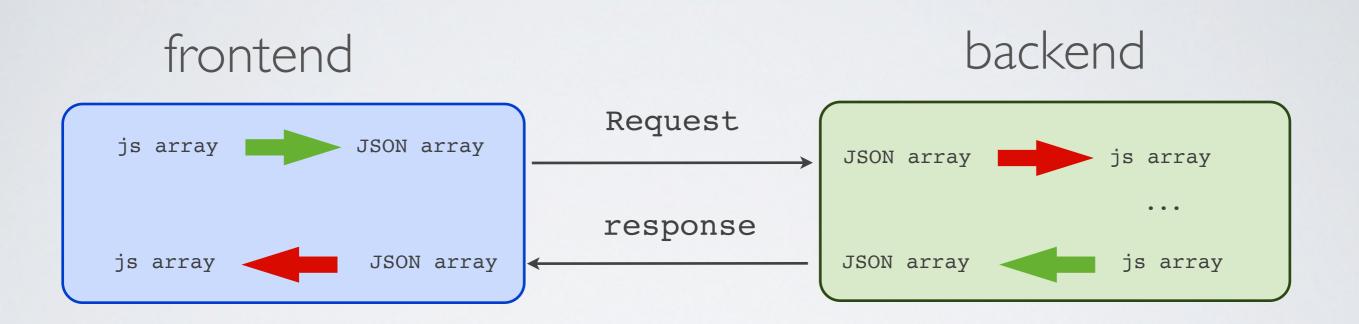

Serialization Javascript - JSON

const myJSONText = JSON.stringify(myObject);

**Deserialization** Javascript — JSON

const myObject = JSON.parse(myJSONtext)

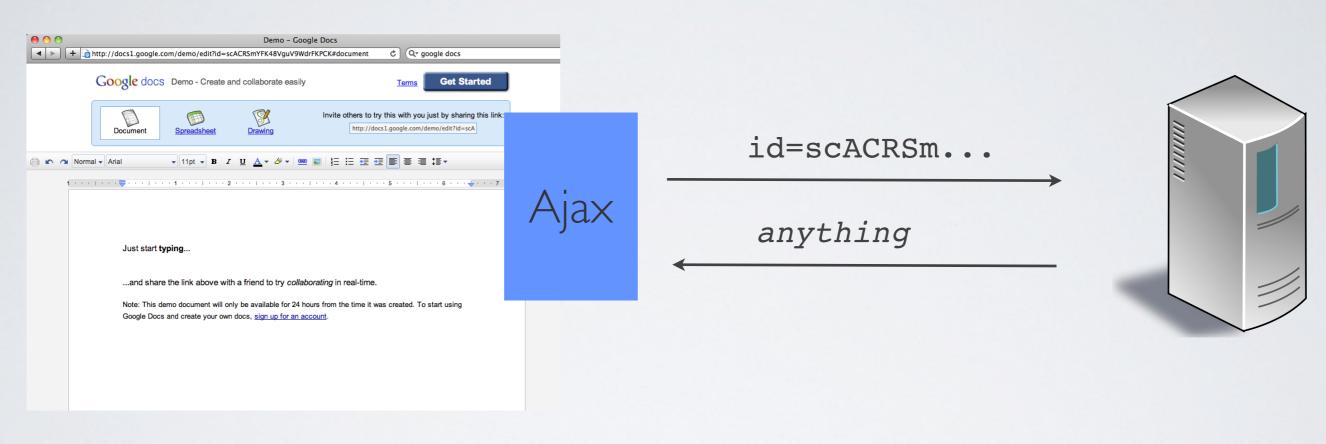

#### Serialization - Deserialization

# AJAX Asynchronous Javascript and XML and JSON

#### Ajax - fetching data without refreshing the page

Javascript

#### Why do we need Ajax?

So far, when we wanted to

- send data to the server
- or retrieve data from the server
- we had to refresh the entire page
   (i.e reloading HTML, CSS, JS and all media files)
- ✓ But, why not using Javascript to process the data and perform the necessary page changes?

#### Ajax - Asynchronous Javascript And XML

Fetch/push content from/to the server asynchronously i.e without having to refresh the page

- Ajax is not a language
- √ It is a simple Javascript command

#### History of Ajax

- Patent from Microsoft (filled in 2000, granted in 2006)
  - XMLHTTP ActiveX control (Internet Explorer 5)
- Adopted and adapted by Opera, Mozilla and Apple
  - XMLHttpRequest Javascript object (standard)
- Before / After IE7
  - Different code for different browser (emergence of the javascript framework *Prototype*)
  - √ Javascript Object was adopted by IE7

#### Ajax revolutionized the Web

- ✓ Started with Gmail and Google Maps
- Advantages
  - Low latency
  - Rich interactions
- Consequences
  - Webapp center of gravity moved to the client side
  - Javascript engine performance race

## Standard Ajax

```
const xhr = new XMLHttpRequest();
xhr.onload = function(){
  if (xhr.status !== 200)
     console.error("[" + xhr.status + "]" + xhr.responseText);
  else
     console.log(xhr.responseText);
};
xhr.setRequestHeader(key, value);
xhr.open(method, url, true);
xhr.send(body);
```

(always) asynchronous

## Concurrency issue in Ajax - a typical example

```
initialization
              11 11
let result =
                                            asynchronous
const xhr = new XMLHttpRequest();
xhr.onload = function (){
                                            assignment
         result = xhr.responseText;
xhr.open(method, url, true);
xhr.send(body);
document.getElementById.innerHTML = result;
                                                   access
```

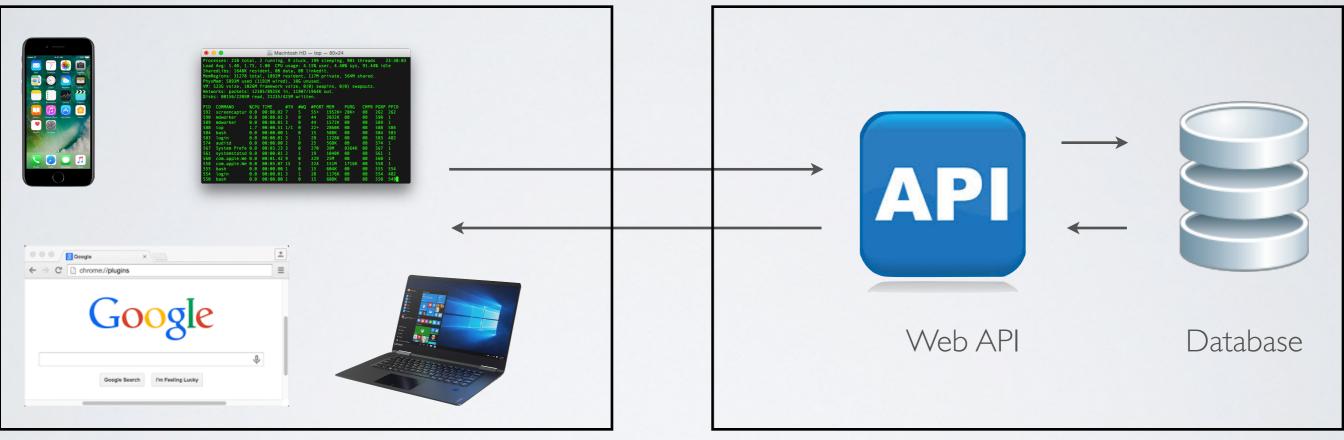

result will either be "" or "Hello world" depending on the program and the execution context

**→** Race Condition!

(REST) Web API

#### Modern Web Platform

## Client Side Server Side

The server side is more or less of a storage system

### REST - Representational State Transfer

Design a remote API for a storage system by using HTTP

- Function names: method and URL
- Function arguments: URL and request body
- Returned value : status code and response body

## REST concepts

Mostly storage systems are meant to store

- Collections (or ressources)
- Elements that belongs to one or several collections

# Examples

	HTTP request	HTTP response
Create a new message	POST /messages/ "Hello World"	200 "78"
Get all messages	GET /messages/	200 "['Hello world',]"
Get a specific messages	GET /messages/78/	200 "Hello World"
Delete a specific messages	DELETE /messages/78/	200 "success"

## Relationships

Туре	Example	
one-to-one	/users/sansthie/profile/firstname/	
one-to-many	/users/sansthie/messages/89/	
many-to-many	/users/sansthie/teams/8/ /teams/8/users/sansthie/	

## CRUD - manipulating data

Basic functions of persistent storage

- Create
- Read
- Update
- Delete

# Query methods

CRUD	HTTP	Collection	Element
Create	POST		Create a new element
	PUT	Replace the entire collection	Create (or replace if exists) a specific element
Read	GET	List all elements	Retrieve a specific element
Update	PATCH	Update some attributes of some elements	Update some attributes of a specific element
Delete	DELETE	Delete the entire collection	Delete a specific element

### Status codes

http://www.restapitutorial.com/lessons/httpmethods.html

### Use of attributes

Query a subset of a collection : filter, page, range . . .

GET /messages/?from=67&to=99

### Alternative to REST for data exchange

- SOAP (legacy)
- GraphQL (consistency)
- gRPC (performances)
